# A sensitivity tuneable tetraphenylethene-based fluorescent probe for directly indicating the concentration of hydrogen sulfide<sup>†</sup>

Yunbo Cai,<sup>a</sup> Lingzhi Li,<sup>a</sup> Zongtan Wang,<sup>a</sup> Jing Zhi Sun,<sup>a</sup> Anjun Qin\*<sup>ab</sup> and Ben Zhong Tang\*<sup>abc</sup>

## A novel tetraphenylethene-based fluorescent $H_2S$ probe was designed and synthesized, which exhibited high selectivity and tuneable sensitivity, making direct indication of $H_2S$ concentration in blood and unknown samples possible.

Hydrogen sulfide ( $H_2S$ ) has been regarded as a toxic gas with unpleasant rotten egg smell for a long time. However, recent studies suggest that  $H_2S$  is also an important endogenous gasotransmitter existing in the human body and other biological systems.<sup>1</sup> The significance of  $H_2S$  has been validated in various physiological processes, such as the regulation of cell growth,<sup>2</sup> cardiovascular protection,<sup>3</sup> the stimulation of angiogenesis,<sup>4</sup> the antioxidative effect,<sup>5</sup> modulation of neuronal transmission,<sup>6</sup> and the anti-inflammation effect.<sup>1b</sup> It has also revealed that the deregulation of  $H_2S$  is related to the symptoms of Alzheimer's disease, diabetes, *etc.*<sup>7-10</sup>

It is highly urgent to understand the physiological and pathological functions of  $H_2S$ , but the contribution of  $H_2S$  to the human body and other biological systems, and the underlying molecular events remain unknown. Therefore, accurate and reliable detection of  $H_2S$  and direct indication of its concentration are desirable in order to provide useful information to study the function of  $H_2S$  in depth. In recent years, the detection of  $H_2S$  has become a hot research area, and a series of methods for sensing  $H_2S$  have been developed, such as colorimetry,<sup>11</sup> electrochemical analysis,<sup>12</sup> and gas chromatography.<sup>13</sup>

Among these reported technologies, the fluorescent method has drawn much attention because of its high sensitivity, high selectivity, simplicity, and non-destructive advantage.<sup>14</sup>

For the design of fluorescent  $H_2S$  probes, one of the most prevalent strategies is to reduce the non-emissive azido-containing fluorophores to the corresponding emissive amino derivatives, in which the sensing mechanisms of fluorescence resonance energy transfer (FRET) or excited-state intramolecular proton-transfer (ESIPT) was mostly employed.<sup>15</sup> Generally, such measurements were carried out in aqueous solution and the traditional hydrophobic emissive amino derivatives suffer from the notorious aggregation-caused quenching (ACQ), which has greatly decreased their sensing performance.<sup>16</sup>

Since the detection of  $H_2S$  in the biological systems will be carried out in aqueous solution, research has to take tedious processes to make the probes water-soluble to enhance the sensitivity. The alternative facile strategy is to take advantage of the aggregation of the hydrophobic probes in the aqueous solution, that is, to develop the systems that the aggregation of the reduced products enhances instead of quenching the emission.

Indeed, we have observed such systems: a series of propellershaped non-emissive molecules in solutions, such as silole and tetraphenylethene (TPE), are induced to emit efficiently by aggregate formation.<sup>17</sup> This unique photophysical process has been termed as aggregation-induced emission (AIE).<sup>18</sup> The AIE phenomenon is exactly opposite to the ACQ effect, and the AIE-active luminogens have found wide applications in diverse areas including lightemitting devices, chemosensors and bioprobes. We anticipated that the AIE-active probes will behave differently from the traditional ACQ ones with FRET or ESIPT mechanisms. To the best of our knowledge, there is no probe used for H<sub>2</sub>S detection based on the AIE process was reported.

For the traditional  $H_2S$  detection systems, the emission of the reduced products gradually intensified with the addition of  $H_2S$  and no tuneable sensitivity was reported. This linear relationship makes the direct indication of the  $H_2S$  concentration in its containing samples time-consuming because the work plot has to be first figured out. Furthermore, as far as we

 $<sup>\</sup>dagger$  Electronic supplementary information (ESI) available: Synthetic details of probes, IR,  $^1H$  and  $^{13}C$  NMR spectra of probes and PL spectra of probes upon addition of H\_2S. See DOI: 10.1039/c4cc02844a

know, there is no fluorescent probe for detection of  $H_2S$  with tuneable threshold. With such a feature, it is facile to indicate the  $H_2S$  concentration in an unknown sample by addition of it into the probe solutions with different concentrations, which will be benefit to fast diagnose certain diseases over the traditional linearly responsive probes.

Our groups have been working on the development of new polymerization reactions based on triple-bond building blocks.<sup>19</sup> During the course, we have succeeded in establishing the powerful azide-alkyne click polymerization,20 by which the AIE-active polytriazoles have been prepared from TPE-functionalized diazides. Interestingly, although TPE is AIE-active, the azido functionalized TPE (TPE-Az) is non-emissive in both solution and aggregate states, while the amino group functionalized TPE (TPE-Am) features the AIE effect and is emissive in its aggregate state (Fig. S1 in ESI<sup>+</sup>).<sup>21</sup> Combining the fact that H<sub>2</sub>S could reduce the azido group to the amino one, we thus applied TPE-Az for the detection of H<sub>2</sub>S. The results showed that the non-emissive nature (off) of DMSO solution of TPE-Az became luminescent (on) upon incubation with NaHS (a commonly used hydrogen sulfide source) and generation of aggregates by adding 80 vol% 2-[4-(2-hydroxyethyl)-1-piperazinyl]ethanesulfonic acid (HEPES, (pH = 7.4)) buffer into the solution. More importantly, thanks to the AIE feature of TPE-Am, the detection threshold could be facilely fine-tuned by varying the concentration of TEP-Az, which is rarely reported too.

The probe of 1-(4-azidophenyl)-1,2,2-triphenylethene (denoted TPE-Az), whose structure is shown in Fig. 1, was prepared according to our previously published procedures.<sup>22</sup> For comparison, the reduced product of TPE-Am *i.e.* 1-(4-aminophenyl)-1,2,2-triphenyl-ethene was also prepared by cross-coupling of benzophenone and 4-aminobenzophenone *via* the McMurry reaction in 51.2% yield.<sup>21</sup> The detailed synthesis procedures are given in ESI† and their structures were fully characterized using <sup>1</sup>H, <sup>13</sup>C NMR, FT-IR, and element analysis, and satisfactory data were obtained (Fig. S2–S9, ESI†).

We first recorded the photoluminescence (PL) spectra of TPE-Az and TPE-Am (10  $\mu$ M) in DMSO-HEPES buffer mixtures (v/v = 2:8), in which the molecules become aggregates. The results confirmed our previous observation that the TPE-Az is non-emissive and its spectrum is almost a flat line parallel to the abscissa and the quantum yield is calculated to be 0.36% due to the quenching effect of azido groups (Fig. 2), while remarkable increased emission (*ca.* 60-fold) peaked at 493 nm was recorded upon incubating with 5 equivalents of NaHS for 5 min. Moreover, the emission profile is almost the same as that of TPE-Am, which has a quantum yield of 3.20%, further

Fig. 1 Schematic illustration of detection of hydrogen sulfide by the azido-containing fluorophores.

**Fig. 2** (A) PL spectra of TPE-Az, TPE-Am, and TPE-Az after incubation with 50  $\mu$ M H<sub>2</sub>S in DMSO-HEPES buffer (10 mM, pH = 7.4) mixtures with the buffer fraction of 80%. Inset: photograph of (1) TPE-Az, (2) TPE-Az + H<sub>2</sub>S and (3) TPE-Am under a UV lamp with a wavelength of 365 nm in DMSO-HEPES buffer mixtures with the buffer fraction of 80%. (B) Time-dependent PL change of TPE-Az upon addition of 50  $\mu$ M H<sub>2</sub>S in DMSO-HEPES buffer mixtures with the buffer fraction of 80%. Concentration of TPE-Az and TPE-Am: 10  $\mu$ M;  $\lambda_{ex}$  = 340 nm.

manifesting that TPE-Az could be efficiently converted into TPE-Am (Fig. 2A) in the presence of  $H_2S$ .

Since the catabolism of  $H_2S$  is very fast *in vivo* but it was reported that most of the  $H_2S$  probes display slow response time (more than 20 min) *in vitro*,<sup>15*a*</sup> we thus performed the time-dependent PL measurement to study the kinetics of our probe. As shown in Fig. 2B and Fig. S10 (ESI<sup>†</sup>), the emission intensity was enhanced swiftly within 2 min and saturated afterward when the TPE-Az with a concentration of 10  $\mu$ M was reacted with 50  $\mu$ M of  $H_2S$  in DMSO and then aggregated by addition of 80 vol% of the HEPES buffer. The shorter response time suggests that TPE-Az is more suitable for real time detection of  $H_2S$ . To enable the azido group to be completely reduced to an amino group, a time scale of 5 min was used after addition of  $H_2S$  in our experiments.

Encouraged by the distinct PL changes of TPE-Az upon treatment with  $H_2S$ , we further evaluated the specific nature of this probe by co-incubation with various anions (CO<sub>3</sub><sup>2-</sup>,  $S_2O_3^{2-}$ ,  $SO_4^{2-}$ ,  $Br^-$ ,  $Cl^-$ ,  $HCO_3^-$ ,  $NO_3^-$ ,  $OAc^-$ ,  $OH^-$ ,  $NO_2^-$ ,  $PO_4^{3-}$ ,  $S_2O_4^{2-}$ , and  $SO_3^{2-}$ ; 50 µM), cellular signaling molecule (NO) and biothiols (cysteine, 1 mM; glutathione, 5 mM; and homocysteine, 50 µM). As can be seen from Fig. 3 and Fig. S11 (ESI<sup>†</sup>), these competitive species did not cause any PL changes of the aggregates of TPE-Az, and only  $H_2S$  could lead to pronounced PL enhancement. The excellent selectivity for  $H_2S$  over other reactive analytes shows that the hydrophobic TPE-Az is promising for the detection of  $H_2S$  in a complex biological environment by taking advantage of AIE features of its reduced product of TPE-Am.

Having demonstrated the selectivity of TPE-Az for the detection of  $H_2S$ , we next investigated its ability to quantify the  $H_2S$  concentration. TPE-Az with a concentration of 10  $\mu$ M was first incubated with different amounts of  $H_2S$  (0–50  $\mu$ M) in DMSO for 5 min and then 80 vol% of HEPES buffer was added (Fig. 4 and Fig. S12 and S13, ESI†). To our surprise, no obvious PL signal was recorded when the concentration of the added NaHS was below that of the probe (10  $\mu$ M) (Fig. 4). Afterward, the

**Fig. 3** Selectivity of TPE-Az with other reactive anions, cellular signaling molecule, and biothiols in DMSO-HEPES buffer mixtures with the buffer fraction of 80%. Concentration: probe: 10  $\mu$ M, analytes: 1 mM for Cys, 5 mM for GSH and 50  $\mu$ M for others, HEPES buffer (10 mM, pH = 7.4),  $\lambda_{ex}$  = 340 nm. Cys = cysteine; Hcy = homocysteine; GSH = glutathione. Inset: photographs of TPE-Az with these analytes incubated for 5 min and then generated aggregates (observed under a UV lamp with a wavelength of 365 nm).

Fig. 4 Relative PL intensity of TPE-Az and DPE-Az vs. the concentration of H<sub>2</sub>S in DMSO–HEPES buffer mixtures with the buffer fraction of 80%.  $\lambda_{ex}$  = 348 nm for DPE-Az and 340 nm for TPE-Az.

emission intensity increased swiftly and reached the plateau when 3 equivalents of NaHS were added.

Attracted by this abnormal phenomenon, we varied the concentrations of TPE-Az from 10 to 20 and 50  $\mu$ M and added NaHS into them under the same experimental conditions (Fig. S14–S17, ESI†). As expected, the detection thresholds for H<sub>2</sub>S also varied from 10 to 20 and 50  $\mu$ M. These results clearly demonstrate that the detection of H<sub>2</sub>S by the TPE-Az has a threshold concentration in the aggregate state, below which no PL signal was observed, whereas, above which the emission intensity increased swiftly. Furthermore, this threshold is the same as the concentration of TPE-Az and is tuneable in a wide range by simply varying the concentration of TPE-Az, which covers the typical H<sub>2</sub>S concentration in blood. Thus, this probe

is promising to fast indicate the  $H_2S$  concentration in an unknown sample.

At first, we proposed that without reaching the equivalent of NaHS, TPE-Az is partially reduced. The remaining azido groups in the random mixed aggregates could still quench the emission of the formed TPE-Am, thus making the whole system non-emissive. When an equivalent of NaHS was added, all the azido groups should theoretically be reduced to amino ones, which should make the aggregates of TPE-Am highly emissive. But, according to our experiments, the emission of the system could not be recorded until more than one equivalent of NaHS was added. Thus, we proposed another more reasonable pathway as shown in Fig. S20 (ESI<sup>+</sup>). TPE-Az could probably be first reduced to a nonemissive intermediate TPE-AzS by one equivalent of NaHS, which could be further converted to TPE-Am upon addition of another batch of NaHS.<sup>23</sup> This hypothesis could be confirmed by following experiments. At first, when mixing the TPE-Az with NaHS in equivalent, no PL signal from the aggregates was observed even after 20 min. Meanwhile, when the NaHS reached 2 equivalents, all the TPE-Az could be reduced to TPE-Am but the reaction rate is not high enough to accomplish in 5 min due to the fact that the emission of the system could be further intensified. The reaction could finish upon addition of more NaHS, such as 3-5 equivalents, or prolonging the time from 5 to 11 min. It is worth noting that these two strategies led to the plateau with nearly the same emission intensity (Fig. S21, ESI<sup>†</sup>).

To have a better illustration of the advantage of our probe based on AIE features, we designed and synthesized an azidecontaining diphenylethene (denoted DPE-Az) and AIE-inactive DPE-Am, the reduced product of the former (their structures are shown in Fig. 1, and the synthesis procedures are provided in ESI<sup>†</sup>).<sup>24</sup> Similar to TPE-Az, DPE-Az is also non-emissive in solution and aggregated states. Upon addition of NaHS to the system of DPE-Az under exactly the same experimental conditions as those of TPE-Az, the emission intensity almost linearly increased in the concentration range of 0–20  $\mu$ M (Fig. 4 and Fig. S18 and S19 in ESI<sup>†</sup>). Meanwhile, the emission immediately occurred even when only 0.1 equivalent of NaHS was added into the system and no threshold was recorded, which is well coincident with the reported traditional probes.

In summary, different from the reported traditional fluorescent probes for the detection of H<sub>2</sub>S, which are dominated by the mechanism of the FRET and ESIPT processes, we present here a unique probe based on the AIE feature in the aqueous solution. TPE-Az is non-emissive in solution and aggregate states but could be reduced to the AIE-active TPE-Am by NaHS, a commonly used hydrogen sulfide source. The response time for TPE-Az for the detection of H<sub>2</sub>S could be as short as 2 min, which is much faster than the reported probes. More importantly, the TPE-Az has a detection threshold and could indicate the concentration of H<sub>2</sub>S simply by the lighting up of its emission when TPE-Am formed aggregates. Furthermore, the detection threshold could be finetuned in a wide range by varying the concentration of TPE-Az. Thus, this method is promising to be developed into a facile tool for direct indication of the H2S concentration in blood or unknown samples.
